

# THE nibble ILLUSTRATOR

## The NIBBLE Illustrator

by Colin French  
2144 Iris St.  
Ottawa, Ontario  
Canada, K2C 1B3

### INTRODUCTION

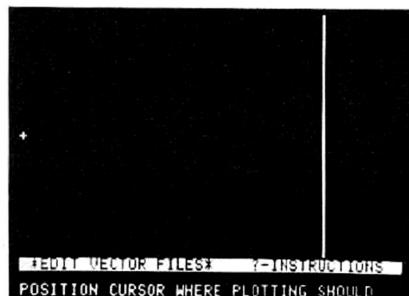

High resolution graphics shapes can easily be displayed on the Apple II Plus by using the built-in shape table commands (see the Applesoft Reference Manual). Unfortunately, constructing the tables to use with these commands is tedious and prone to error. The **NIBBLE Illustrator** allows you to quickly develop complex shape tables for use in your own programs.

The program is divided into two main parts. The first section, **EDIT VECTOR FILES**, is used to design and edit individual shapes. The set of vectors describing the shape is saved to disk, creating a disk 'library' of various shapes. The second section, **BUILD SHAPE TABLE**, combines the shapes from this library in any combination to form completed shape tables. By saving each shape separately it can be easily used in many shape tables, thereby eliminating the need to re-draw shapes for each table.

### USING THE ILLUSTRATOR

In order to explain the various functions of the Illustrator, let's develop a typical shape table. This table will be a sample NIBBLE Logo.

Run the NIBBLE ILLUSTRATOR program and select **EDIT VECTOR FILES** from the menu. We now have a chance to move the cursor to any starting point, so we'll move it to the left side of the screen and press the space bar.

POSITION CURSOR WHERE PLOTTING SHOULD BEGIN, THEN PRESS THE SPACE BAR

Hold down the 'CTRL' key and press the 'I' key. The block the cursor was on is now plotted and the cursor moved up one square. The right side of the screen should show two isolated dots.

We can plot a block and move up, left, right or down by holding the CTRL key and pressing the I, J, K or M keys respectively. To move the cursor without plotting a block, press just the direction key without holding down the CTRL key. This creates a no-plot vector.

By plotting blocks and moving the cursor, sketch out the shape you wish for the logo. This shape will be seen in Hi-res on the right side of the screen both in the normal orientation and turned 90 degrees. These shapes are drawn in white; to see what they will look like drawn in the other Hi-res colors, press the C key to cycle through the four colors and white.

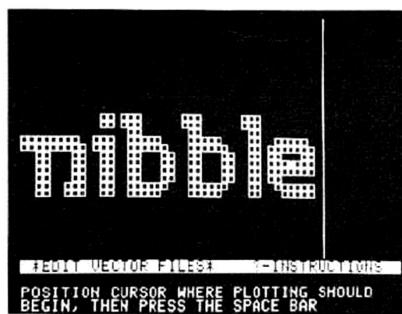

If you make an error you can back up and erase one vector each time you press the B key.

To start over again with a clean screen, press the E key to erase the entire shape and its vectors.

### RE-PLOT THE SHAPE

Once the Nibble logo shape is just right, you could immediately save the set of vectors you plotted, but chances are there are some extra, unneeded vectors in the shape. Since every two vectors use up one byte of memory, it is useful to minimize the number of vectors used to draw a shape. This will also allow the program to draw the shape as quickly as possible. For this sort of shape, plotting should begin at the shape's supposed center of gravity to ensure that it can be made to rotate in a convincing way. To do all of this we can re-plot the shape by pressing the R key. The vectors of the shape are erased, and the solid blocks of the large shape are replaced with empty ones to provide a guide to trace over.

POSITION CURSOR WHERE PLOTTING SHOULD BEGIN, THEN PRESS THE SPACE BAR

Move the cursor using the I, J, K and M keys to the center of the shape and press the space bar. Now plot the shape in the usual manner, copying over the empty blocks in the shortest possible path.

### THE VIEW OPTION

To get a better idea of what the shape will look like, press the V key to **VIEW** the shape. Now besides controlling the color, you may change the scale and rotation of the shape. Because of the way Applesoft draws shapes there are fewer angles of rotation available at smaller scale factors. In fact, at a scale of 1 there are only 8 possible orientations.

The shape may also be moved about the screen by using the I, J, K and M keys. Use these and the 'REPT' key to get a rough sort of animation. Use the 'ESC' key to return to the plotting function.

### SAVE AND LOAD

Save the set of vectors describing the shape by pushing the S key. Use a name such as **NIBLOGO** and the file will be saved as **VECTORS/NIBLOGO**. To make sure the vector file was saved, press the D key for DOS and check the disk catalog by pressing the C key. You can also delete files from this point, but note that the program does not automatically supply the **VECTORS/** prefix used by the **SAVE** shape and **LOAD** shape functions.

Pressing L key will load a shape from disk. Besides being shown in Hi-res, the shape will also be drawn in the enlarged size for use in the PLOTTING or RE-PLOT functions. The plotting of this large shape will begin at the cursor position. If the shape will not fit, you will be prompted to move the cursor to a different location and try again. As always, you can use ESC to escape back to the plotting function.

Return to the plotting function and erase the screen. Repeat the previous steps to design and save another shape under the name **SHAPE2**.

### BUILD THE SHAPE TABLE

We now have two shapes saved to disk to be combined into a shape table. Press the 'ESC' key to escape from the PLOTTING function to the main menu and select **BUILD SHAPE TABLE** by pressing the B key.

The program will prompt you for the names of the shapes to be included in the table. Type in **NIBLOGO** and **RETURN**, and that vector file will be loaded in from disk. The subsequent vector file (**SHAPE2**) you specify will be added to the end of the table. To check the disk catalog enter a 'C' and press 'RETURN' when prompted for a name.

When the two shapes have been loaded, type **END** and press **RETURN** and the program will construct the header of the table. The total length will be displayed, and then you will be prompted for a name to save the table under. Unless you choose to construct another table, you will then be returned to the main menu.

To check the table, select **VIEW SHAPE TABLE** from the main menu and enter your table's name when prompted. You can choose any shape from the table and display it with control over scale, color and rotation in the same manner as **VIEW** of **EDIT VECTOR FILES**. You can also use it to construct pictures using **NIBBLE DESIGNER** in this issue.

### LOADING THE ILLUSTRATOR

To use this program you must have a 48K Apple II with Applesoft in ROM or Language Card and one disk drive. Due to the size of the program, it must be loaded above the High Resolution Graphics Screen 1. This is accomplished with the first line of the Applesoft program in Listing One.

First enter the Applesoft program and **SAVE** it under the name **NIBBLE ILLUSTRATOR**. Then use the monitor to enter the **shape table** shown in Listing Two. (See the Letters section.) Cheer up! It's the last shape table you'll have to enter by hand! Save the table under the name **ITABLE** so the main program can load it correctly. The command is **BSAVE ITABLE, A\$300, LS29**.

## NIBBLE ILLUSTRATOR

Now RUN. Test out the various subroutines to see if they work. The shape table should draw the cursor shape, a cross, and the solid block which appears when you plot a point. Exit the program and add the other functions, testing each as you complete it.

### HOW THE ILLUSTRATOR WORKS

The first line of the Illustrator program resets the high byte of the start of program pointer from \$08 to \$40, thereby causing the program to be re-loaded starting at \$4001. The memory space between the top of Text Page 1 (\$800) and the bottom of the HGR1 screen (\$2000) is used for the shape table or vector file being developed. The shape table used by the main program is located starting at \$300. Having two shape tables requires setting the shape table address pointer correctly before drawing a particular shape, for example in line 1030 of the DRAW/ERASE CURSOR subroutine.

**The vectors of the first shape are poked into memory starting at location \$A01. This allows enough room for the header of a shape table containing 255 shapes and space for over 11,000 vectors.**

### Memory Usage

\$FFFF	DOS, Applesoft and Monitor
\$9600	Main program, strings and variables
\$4000	High Resolution Screen 1
\$2000	Vectors
\$0A01	User Shape Table Header
\$0800	Text Page 1
\$0400	Program Shape Table
\$0300	For computer's use - pointers, etc.
\$0000	

### THE PROGRAM

There are a few interesting sections of the program I'd like to point out, but before discussing these it might be useful to have an overview of the program. The main program is composed of the following sections:

#### 10 - 290 Program Lead and Initialization

#### 400 - 630 Main Menu

#### ----- Subroutines -----

700 - 830	Multi-letter Input
1000 - 1050	Draw/Erase Cursor
1100 - 1170	Draw/Erase Small Shapes
1200 - 1250	Draw/Erase Block
1300 - 1430	Position Cursor
1500 - 1690	Convert Byte to Binary String
1700 - 1940	Draw Large Shape

#### ----- Section 1 Edit Vector Files -----

2000 - 2870	Plotting Function
3000 - 3230	Back Up One
3400 - 3520	Save Vector File
3600 - 3780	Load Vector File
3900 - 4110	DOS Commands
4200 - 4550	View Shape

#### ----- 5000 - 5160 Disk Error Handling -----

#### ----- Section 2 Build Shape Table -----

6000 - 6530	Build Shape Table
7000 - 7550	View Shape Table

#### ----- 8000 - 9460 Instructions -----

#### MULTI-GET FOR INPUT

Using Applesoft's **GET** command for input of information has many advantages when trying to develop a bomb-proof program. However, there are times when more than a single character is required as input. This led to the development of the **Multi-letter Input Subroutine**. After the main program has prompted the user for information, it sets the variable **LMT** to the maximum length of input string that will be allowed and jumps to this routine. The input subroutine basically **GETs** one character at a time, and adds it to the input string variable **WS**. Checks can be made to trap any undesired character. For example, line 780 doesn't allow commas to be accepted. To permit changing the input string, the routine traps the Back-up-arrow key and modifies the display and string accordingly. Upon return to the main program, **WS** holds the user's input.

#### PLOTTING

The **PLOTTING** function starts with a straightforward initialization of the vectors, Hi-res screen and text window, followed by

branches off to the various other functions of EDIT VECTOR FILES. Next comes the most important part of the function: poking the vectors into memory. I decided to have only two vectors per byte, as it is rare that three vectors can be fitted into one byte, and it simplifies the program considerably. The program determines which vector you have entered, plots the block in the large shape if it is a plot-type vector, changes the cursor coordinates to match the desired direction, and finally does the poke into the proper memory location.

The only exception to this procedure is the **up-no-plot vector**. If it is the second vector of a byte, the Applesoft Draw routine will ignore it and jump to the next byte. If it is the first vector and the second vector is anything other than another up-no-plot vector, everything works properly. But if **both vectors of the byte are up-no-plot, the Applesoft routine would interpret this as the end of the shape and stop drawing completely. The code from line 2620 to line 2660 checks for these troublesome situations and corrects them.** If the up-no-plot is the second vector it is simply moved to become the first vector of the next byte. If you follow one up-no-plot with another, the program adds a vector to sidestep to the left, does the up-no-plot, then steps back over to the right. All of this goes on without you knowing it, but if you back up over a couple of up-no-plot vectors, the sidestep becomes apparent.

Throughout the program the variable **LOC** is assigned different values. These indicate the location of the user in the program and therefore what function is being used. This information is used by two sections of the program, the DISK ERROR HANDLING and INSTRUCTIONS functions, to return you to the proper place in the program after error messages or instructions have been printed.

#### MODIFICATIONS AND IMPROVEMENTS

As the program stands, it provides a **44 by 32 square grid** in which to plot shapes, with each square of the grid occupying 5 by 5 Hi-res points. You might want to try different sizes of grids. Using a 4 by 4 point square would allow a 55 by 40 grid, but the smaller size of the square makes it more difficult to design distinguishable shapes for the cursor and the two types of blocks. Those of you with monitors could probably get away with a 3 by 3 point square.

```

Another improvement would be to write a machine language routine to take the place of the DRAW LARGE SHAPE subroutine. This could be much the same as the Applesoft Draw routine, but instead of plotting just a point it would draw a pre-defined shape with each vector. The increased speed of this approach could open up all sorts of other modifications such as relocating the large shape within the grid if you run out of room for plotting along one side.

## CONCLUSION

I hope you will find this program as valuable as I do. You can try many things with shape tables that you've probably been itching to do. The first project I used this program for was to create a 3000-vector shape table for use in a fancy introduction for my own copy of the program. Another useful project is to

create an alphabet, including lower case, to use on the Hi-res screen. As you work with the program you will find that more, and more possibilities will present themselves.

**ED. NOTE:** The NIBBLE diskette contains shape tables for Electronics and full alpha/numerics at both standard and double sizes. It also contains vector tables for a space ship and an Apple.
